LLM Response:
**Artificial Intelligence (AI)** is simply when computers or machines are taught to **think, learn, and make decisions** like humans do.

Normally, a computer can only do what a human explicitly programs it to do. But with AI, the computer can learn from experience, spot patterns,
 and solve problems on its own.

Here is an easy way to understand it:

### How does AI learn?
Think of AI like a child learning new things:
* If you show a child thousands of pictures of cats, the child eventually learns what a cat looks like.
* AI works the same way. You feed it massive amounts of information (data), and it teaches itself to recognize patterns.

### Everyday examples of AI:
You probably use AI every day without realizing it:

1. **Smart Assistants:** Siri, Alexa, and Google Assistant understand what you say and answer your questions.
2. **Recommendations:** Netflix suggesting a movie you might like, or Spotify creating a playlist for you.
3. **Navigation:** Google Maps predicting traffic and finding the fastest way home.
4. **Facial Recognition:** Your smartphone unlocking just by looking at your face.
5. **Chatbots:** Tools like ChatGPT that can hold conversations, write essays, or answer questions.

### In short:
Regular software follows rules written by humans. **AI creates its own rules by learning from information.** Its goal is to make life easier by
 doing tasks that usually require a human brain.
